(57) **ABSTRACT**

A memory system includes first and second districts, and a control section. Each of the first and second districts includes a memory cell array. The control section receives a single write command to simultaneously write first data to the first and second districts. A memory controller may subsequently issue a read command to read the first data from one of the memory cell arrays to determine whether the read first data is normal or is correctable based on a result of error correction in an error correction circuit. When the read first data is normal or is correctable, the first data written to the other of the memory cell arrays may be deleted or nullified.

# MEMORY SYSTEM PROVIDED WITH NAND FLASH MEMORY AND METHOD INCLUDING SIMULTANEOUSLY WRITING DATA TO FIRST AND SECOND MEMORY ARRAYS

## CROSS-REFERENCE TO RELATED APPLICATIONS

This application is based upon and claims the benefit of priority from prior Japanese Patent Application No. 2011-208105, filed Sep. 22, 2011, the entire contents of which are incorporated herein by reference.

## FIELD

Embodiments described herein relate generally to a semiconductor memory device, for example, a memory system provided with a NAND flash memory, and method of controlling the same.

## BACKGROUND

Recently, memory capacity of a NAND flash memory has increased, and the number of word lines in one chip has also increased.

In writing of data, an error in part of bits in one page selected by one word line can be corrected by using an error correction code (ECC). However, it is difficult to correct an error or omission in data in units of pages by using an ECC.

Accordingly, heretofore, in order to protect data in units of pages, data identical to the data to be written is written to an area different from the data to be written to thereby prepare a backup.

However, in order to record identical data such as the backup in a different area, it is necessary to write the identical data twice, and hence extra time has been required to write data, and the system throughput has been lowered. Thus, for this reason, a memory system enabling data to be written securely at high speed is desired.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram schematically showing a memory system applied to an embodiment.

FIG. 2 is a block diagram showing part of the memory system of FIG. 1.

FIG. 3 is a view showing an example of a command sequence according to a first embodiment.

FIG. 4 is a view showing an example of a conventional command sequence.

FIG. 5 is a view shown to explain a write operation of first and second districts.

FIG. 6 is a flowchart showing an operation of a second embodiment.

FIG. 7 is a flowchart showing an operation of a third embodiment.

## DETAILED DESCRIPTION

In general, according to one embodiment, a memory system includes first and second districts, and a control section. Each of the first and second districts includes a memory cell array. The control section receives addresses and a write command to simultaneously write first data to the first and second districts, and simultaneously writes the first data to the first and second districts.

2

Hereinafter, embodiments will be described with reference to the drawings.

## First Embodiment

FIG. 1 schematically shows a memory system according to this embodiment.

The memory system is constituted of a memory device **11** such as an SD (Secure Digital) card, and host **20**. It should be noted that the memory device **11** does not necessarily have a card-like shape, and may be incorporated in the host **20** in an undetachable manner. The host **20** is also called a host device.

Upon connection to the host **20**, the memory device **11** receives power supply to operate, and carries out processing corresponding to an access from the host **20**. The memory device **11** includes a card controller **11a**.

The card controller **11a** is constituted of, for example, a host interface **12**, CPU (Central Processing Unit) **13**, read-only memory (ROM) **14**, random access memory (RAM) **15**, and buffer **16**. These are connected to each other by a bus. Furthermore, a memory controller **17** is connected to the bus. For example, a NAND flash memory **18** is connected to the memory controller **17**.

The host interface **12** carries out interface processing between the card controller **11a** and host **20**.

The memory controller **17** carries out interface processing between the card controller **11a** and NAND flash memory **18**. Furthermore, the memory controller **17** includes an ECC circuit **17a**, and subjects data supplied from the NAND flash memory **18** to error correction processing by means of the ECC circuit **17a**.

The CPU **13** controls operations of the whole memory device **11**. The CPU **13** receives a write command, read command, erase command, and the like from the host **20**, and accesses an area on the NAND flash memory **18** or controls data transfer processing through the buffer **16**.

The ROM **14** stores therein at least part of firmware such as a control program or the like used by the CPU **13**. The RAM **15** is used as a work area of the CPU **13**, and stores therein a control program, various tables, and an expanded register, described later.

The buffer **16** temporarily stores therein a certain amount of data (for example, data corresponding to one page) when data sent from the host **20** is written to, for example, the NAND flash memory **18**, or temporarily stores therein a certain amount of data when data read from the NAND flash memory is sent to the host **20**.

The NAND flash memory **18** is constituted of, for example, a memory cell of the stacked gate structure or a memory cell of the MONOS (Metal-Oxide-Nitride-Oxide Semiconductor) structure. The NAND flash memory stores therein system software or the like configured to control an operation of, for example, user data, application software or the card controller **11a**. The user data, application software, and system software are managed by a file allocation table (FAT).

On the other hand, the host **20** can be, for example, a digital camera, cellular phone, personal computer, and the like. The host **20** is constituted of a host controller **21**, CPU **22**, ROM **23**, RAM **24**, and, for example, hard disk drive (HDD) **25** (including a solid state drive (SSD)). These are connected to each other by a bus.

The CPU **22** controls the whole host. The ROM **23** stores therein firmware necessary for the operation of the CPU **22**. Although the RAM **24** is used as, for example, the work area of the CPU **22**, a program which can be executed by the CPU **22** is also loaded here in the RAM **24** to be executed. The hard disk **25** retains various data items. The host controller **21**

carries out interface processing between the host and memory device **11** in a state where the memory device is connected thereto. That is, the host controller **21** issues various commands to be described later in accordance with instructions of the CPU **22**.

FIG. **2** shows an example of the NAND flash memory **18** shown in FIG. **1**. The NAND flash memory **18** is constituted of, for example, first and second districts **31a**, and **31b**. The first and second districts **31a** and **31b** have the identical configuration, and hence the first district **31a** will be described and, in the second district **31b**, parts identical to those of the first district **31a** are denoted by identical reference symbols, and a description of them is omitted.

In the first district **31a**, a memory cell array **32** includes, as will be described later, a plurality of blocks BLK**0** to BLK**4095**. Each block is constituted of a plurality of NAND strings. Each NAND string includes a plurality of memory cells MC connected in series, and selection transistors **S1** and **S2** configured to connect the NAND string to a bit line, and source line (not shown). A control gate of each memory cell is connected to a word line WL.

Each word line WL is connected to row decoders **33** and **34**, and a word line is selected by the row decoders **33** and **34**.

Further, each bit line BL is connected to a sense amplifier **35**. Each sense amplifier **35** is connected to each of a plurality of data registers **36**, **37**, and **38**, and a logic circuit **39**. Each sense amplifier **35** detects a voltage of the bit line BL at the time of write, verify, and read of data. The plurality of data registers **36**, **37**, and **38** hold data to be written to the memory cell at the time of write, and verify of the data, and hold data read from the memory cell at the time of read of the data. Each of the sense amplifiers **35**, data registers **36**, **37**, and **38** is made able to hold data of one page. The logic circuit **39** carries out operations such as data transfer between the data registers **36**, **37**, and **38**, and data inversion or the like at the time of data write or data read.

Furthermore, a peripheral circuit **40** is common-connected to the first and second districts **31a** and **31b**. The peripheral circuit **40** includes, for example, an address decoder **41**. The address decoder **41** is connected to an IO (Input Output) pad **42**, decodes an address supplied from the IO pad **42**, and supplies the decoded address to one of the first and second districts **31a** and **31b**.

FIG. **3** shows an example of a command sequence according to the first embodiment.

In the first embodiment, it is made possible to simultaneously write the same data to the first and second districts **31a** and **31b**. Accordingly, a particular write command XX is defined. The symbol "XX" is an identifier of the command, and is not limited to "XX". It is sufficient if the identifier is a symbol or a numeral identifiable in the memory system.

Hereinafter, an operation to be carried out when the memory device **11** receives a "command to duplex the same data to store" from the host device **20** will be described below. The command to duplex the same data to store is input to the memory device **11** through the host interface **12**. The CPU **13** interprets the command, and controls the NAND flash memory **18** in such a manner that the memory controller **17** simultaneously writes the same data to the first and second districts **31a** and **31b**.

Further, the host device **20** may attach a flag bit indicating that the data is important, and requires secure protection to the data to be input to the memory device **11**. The CPU **13** interprets the flag bit, and carries out control in such a manner that the memory controller **17** simultaneously writes the same data to the first and second districts **31a** and **31b**.

Further, when the host device **20** successively inputs the same data to the memory device **11**, the CPU may interpret this to carry out control in such a manner that the memory controller **17** simultaneously writes the same data to the first and second districts **31a** and **31b**.

The memory controller **17** first issues a command XX to simultaneously write the same data to the first and second districts **31a** and **31b** to the NAND flash memory **18** and, subsequently to this, outputs a page address Add (L) in the first district **31a**. Subsequently, the memory controller **17** issues a command indicating that input of a page address is to be successively carried out, such as a command to switch the first or the second district **31a** or **31b** or a command **11h** (h indicates a hexadecimal number) to the NAND flash memory **18**. Thereafter, the memory controller **17** supplies a page address Add (R) in the second district **31b**, write data DT, and command **10h** in sequence to the NAND flash memory **18**. The command **10h** indicates, for example, the tail end of the command sequence. When the command **10h** is issued, a ready/busy signal is set from a ready state to a busy state (B2R), and the data DT is simultaneously written to the page address Add (L) of the first district **31a**, and page address Add (R) of the second district **31b**.

FIG. **4** shows a conventional command sequence. In the command sequence shown in FIG. **3**, after supplying the write command XX to write data to the first and second districts **31a** and **31b**, and page addresses Add (L), and Add (R) from the memory controller **17** to the memory device **11**, the data DT has been supplied from the memory controller **17** to the NAND flash memory **18** only once.

On the other hand, in the conventional duplexing command sequence shown in FIG. **4**, first the write command XX to simultaneously write the same data to the first and second districts **31a** and **31b** is issued, subsequently the address ADD (L), data DT, and command **11h** for the first district **31a** are supplied to the NAND flash memory **18**. After this, the memory controller **17** supplies in sequence the page address (R), and data DT for the second district **31b** to the NAND flash memory **18**, and then issues the command **10h**.

In the case of the command sequence shown in FIG. **4**, it is necessary to supply the same data DT twice from the memory controller **17** to the NAND Flash memory **18**.

FIG. **5** shows a schematic operation to be carried out when the same data is written to the first and second districts **31a** and **31b**.

When the write command XX to write data to the first and second districts **31a** and **31b**, and page addresses Add (L) and Add (R) are supplied from the memory controller **17** to the NAND flash memory **18**, the address decoder **41** supplies the page address Add (L) to the first district **31a**, and supplies the page address Add (R) to the second district **31b**. Further, the data DT supplied to the NAND flash memory **18** is retained in a data register (XDL) **38** of each of the first and second districts **31a** and **31b**. After this, the data retained in the data register **38** is transferred to each of the logic circuit **39**, data registers **37** and **36**, and sense amplifier **35**, and is simultaneously written to pages designated by the page addresses Add (L) and Add (R).

According to the above-mentioned first embodiment, the write command XX to write the same data DT to the first and second districts **31a** and **31b** is defined, and the page addresses Add (L) and Add (R) of the first and second districts **31a** and **31b**, and data DT are supplied in sequence to the NAND flash memory **18** in response to the write command XX, whereby it is possible to simultaneously write the same data to the first and second districts **31a** and **31b**. Accordingly, it is possible to simultaneously write the same data to the first

5

and second districts **31a** and **31b** by the single write command **XX** and, unlike the conventional case, it is not necessary to transfer the same data twice. Accordingly, it is possible to improve the throughput of the write processing.

Further, the same data is simultaneously written to the first and second districts **31a** and **31b**, and hence it is possible to reduce the probability of the write data being destroyed. Accordingly, the command sequence of this embodiment is effective when data difficult to be re-entered such as photographic data is to be securely preserved.

It should be noted that in this embodiment, although the case where the NAND flash memory **18** is provided with two districts has been described, the description can also be applied to a case where the NAND flash memory **18** is provided with three or more districts in the same manner. Further, when the NAND flash memory **18** receives write data without preparing the particular command to simultaneously write the same data to the first and second districts **31a** and **31b**, the same data may be simultaneously written to the first and second districts **31a** and **31b** at all times.

#### Second Embodiment

FIG. 6 is a flowchart showing operation of a second embodiment, and shows, for example, an operation of a memory controller **17**.

In the first embodiment, the same data DT is written to the first and second districts **31a** and **31b** by a single write command **XX**.

Conversely, in the second embodiment, immediately after the same data DT is written to first and second districts **31a** and **31b**, the data of one of the first and second districts is read and, when the data is normal, the data which has been written to the other of the first and second districts is nullified.

That is, when data is written to the NAND flash memory **18**, if data write is completed, status data indicating that data write has normally been completed is output from the NAND flash memory **18**. However, even in this case, there occurs a case where data is destroyed with the advance of data write in the block. Whether or not the data is destroyed is determined by reading the data from the NAND flash memory **18**. When the data has normally been read, it is determined that the block in which the data is recorded is normal. Accordingly, the data of the district including the block for which it is determined that the block is normal is left as it is, and the block including the same data in the other district is nullified.

More specifically, as shown in FIG. 6, in accordance with the first embodiment, the same data DT is written to the first and second districts **31a** and **31b** by the single write command **XX** (ST11).

After this, a read command to read the data DT written to one of the first and second districts **31a** and **31b** is issued from the memory controller **17**. That is, for example, a read command to read the data DT which has been written to the first district **31a** is issued, and the data DT which has been written to the first district **31a** is read (ST12).

The data DT read from the first district **31a** is transferred to the memory controller **17**, and is subjected to the error correction processing by the ECC circuit **17a**. As a result of the error correction processing, it is determined whether or not the read data is normal. That is, it is determined whether or not an error included in the read data is of such a degree that the error can be corrected (ST13).

When the error is of such a degree that the error can be corrected by using the ECC circuit **17a** as a result of the determination, it is determined that the data DT read from the first district **31a** is normal data, and the data of the other of the

6

first and second districts **31a** and **31b**, i.e., in this case, the same data as that of the first district **31a** written to the second district **31b** is nullified (ST14). That is, the block of the second district **31b**, and including the same data as that of the first district **31a** is nullified.

On the other hand, in step ST13 described above, when it is determined that the error of the read data is an uncorrectable error, a read command to read the data DT written to the other of the first and second districts **31a** and **31b**, e.g., the second district **31b** is issued, and the data DT written to the second district **31b** simultaneously with the first district **31a** is read (ST15).

The data DT read from the second district **31b** is transferred to the memory controller **17**, and is subjected to the error correction processing by the ECC circuit **17a**. As a result of the error correction processing, it is determined whether or not the read data is normal. That is, it is determined whether or not the error included in the read data is of such a degree that the error can be corrected (ST16).

When, as a result of the determination, the error is of such a degree that the error can be corrected by the ECC circuit **17a**, it is determined that the data DT read from the second district **31b** is normal data, and data of one of the first and second districts **31a** and **31b**, i.e., in this case, the block in which the same data as that of the second district **31b** written to the first district **31a**, is nullified (ST17).

Further, when, as a result of the determination of step ST16 described above, the error of the read data is an uncorrectable error, both the blocks of the first and second districts **31a** and **31b** each including the same data are erroneous, and hence the data is recognized as data which cannot be corrected even by this system (ST18).

It should be noted that regarding the nullification of the block carried out by the memory controller **17**, it is sufficient if, for example, access to the data is inhibited, and physically deleting the data is not necessary. Further, deletion of data regarded as invalid data is carried out by the memory controller **17** as the need arises.

According to the above-mentioned second embodiment, data DT written to the first and second districts **31a** and **31b** is read from one of the first and second districts and, when the read data is normal, the block including the data DT written to the other of the first and second districts **31a** and **31b** is nullified. Accordingly, it is possible to securely write data to one of the first and second districts **31a** and **31b** by a single command.

For example, in the case where data is to be written to only one of the first and second districts **31a** and **31b** as in the conventional case, when the data write fails, although it is necessary for the memory controller **17** to issue a write command again, and transfer an address and data to the memory device **11**, there is a case where the data has already disappeared from the RAM **15**. For example, when the host **20** is a digital still camera, photographed data is lost.

However, in the case of the second embodiment, the case where both the data items written to both the first and second districts are error-uncorrectable rarely occurs, and hence it is possible to securely write data, and improve the throughput of data write.

Moreover, when the data of one of the districts is normal, the block of the other of the districts including the same data is nullified, and is deleted as the need arises, and hence it is possible to prevent the memory capacity from being reduced.

#### Third Embodiment

In the second embodiment, immediately after the same data is written to each of the designated blocks of the first and

7

second districts **31a** and **31b**, a read command is issued from the memory controller **17** to read data from a designated block of, for example, the first district **31a** and, when there is no error in the read data or when the error can be corrected by ECC processing, it is determined that the data of the first district **31a** is normal, and the block of the second district **31b** including the same data is nullified.

Conversely, in a third embodiment, immediately after the same data is written to each of first and second districts **31a** and **31b**, the written data is not read. In the case of the third embodiment, the data written to each of the first and second districts **31a** and **31b** is regarded as being valid for the time being. That is, both the data items written to the first and second districts **31a** and **31b** are treated as valid until the data item written to the first or second district **31a** or **31b** is read.

In this state, as shown in FIG. 7, upon receipt of a data read request from a CPU **13** (ST21), a memory controller **17** first determines whether or not the same data is written to the first and second districts **31a** and **31b** (ST22). In this case, the memory controller **17** preserves, for example, an issuance history of the write command XX, and page addresses, and the preserved page address and a read address are compared with each other.

When, as a result of the above determination, the same data is written to the first and second districts **31a** and **31b**, the operations of steps ST12 to ST18 shown in FIG. 6 are executed (ST23). That is, data is read from one of the first and second districts **31a** and **31b**. When the read data is normal, the block including the same data recorded on the other of the first and second districts **31a** and **31b** is nullified.

Further, when, as a result the determination of above step 22, it is determined that the same data is not written to the first and second districts **31a** and **31b**, a normal read operation is executed (ST24).

According to the above-mentioned third embodiment, immediately after data is written to the first and second districts **31a** and **31b**, a data read configured to verify whether or not the written data is normal is not carried out, and hence it is possible to reduce the overhead required for the verification. Accordingly, it is possible to enhance the write speed.

It should be noted that in each of the above-mentioned first to third embodiments, the operation of the NAND flash memory including the first and second districts has been described. However, the embodiments are not limited to the above, and it is needless to say that the above embodiments can be applied to a NAND flash memory including three or more districts.

While certain embodiments have been described, these embodiments have been presented by way of example only, and are not intended to limit the scope of the inventions. Indeed, the novel embodiments described herein may be embodied in a variety of other forms; furthermore, various omissions, substitutions and changes in the form of the embodiments described herein may be made without departing from the spirit of the inventions. The accompanying claims and their equivalents are intended to cover such forms or modifications as would fall within the scope and spirit of the inventions.

What is claimed is:

1. A memory system comprising:
  - a flash memory including first and second districts, each of which includes a memory cell array; and
  - a memory controller including an error correction circuit, wherein the memory controller is configured to issue a write command to the flash memory to simultaneously write first data to both of the first and second districts,

8

the flash memory is configured to simultaneously store the first data in both of the first and second districts, the memory controller is configured to issue a read command to the flash memory to read the first data from one of the first and second districts, the flash memory is configured to output the first data read from the one of the first and second districts to the memory controller, the memory controller is configured to determine whether or not the first data read from the one of the first and second districts is correctable based on a result of error correction in the error correction circuit, and the memory controller is configured to perform issuing the write command, and each of issuing the read command and determining whether or not the first data is correctable when executing a data write in reply to the write command.

2. The system according to claim 1, wherein

when the first data read from the one of the first and second districts is correctable, the memory controller is configured to instruct the internal controller to delete the first data written to the other of the first and second districts.

3. The system according to claim 1, wherein

upon receipt of a read instruction from the external host device, the memory controller is configured to determine whether or not the first data has been written to the first and second districts on the basis of a history of write to the first and second districts and, when the first data has been written to the first and second districts, reads the first data from one of the first and second districts.

4. The system according to claim 1, wherein the first district comprises:

- a first memory cell array including a plurality of memory cells;
- a first row decoder configured to select one of the plurality of memory cells of the first memory cell array; and
- a first sense amplifier configured to detect data read from the first memory cell array, and

the second district comprises:

- a second memory cell array including a plurality of memory cells;
- a second row decoder configured to select one of the plurality of memory cells of the second memory cell array; and
- a second sense amplifier configured to detect data read from the second memory cell array.

5. The system according to claim 1, wherein the flash memory includes an address decoder configured to receive first and second addresses, supply the first address to the first district, and supply the second address to the second district.

6. A method of controlling a memory system including a flash memory including first and second districts, the method comprising:

- issuing, by a memory controller, a write command to simultaneously write first data to both of the first and second districts, each of which includes a memory cell array,
- simultaneously storing, by the flash memory, the first data in both of the first and second districts,
- issuing, by the memory controller, a read command to the flash memory to read the first data from one of the first and second districts,
- outputting, by the flash memory, the first data read from the one of the first and second districts from one of the first and second districts, to the memory controller,
- determining, by the memory controller, whether or not the first data read from the one of the first and second dis-

tricts is correctable based on a result of error correction in an error correction circuit of the memory controller, and

performing, by the memory controller, issuing the write command, and each of issuing the read command and determining whether or not the first data is correctable when executing a data write in reply to the write command.

7. The method according to claim 6, further comprising deleting the first data written to the other of the first and second districts when the first data read from the one of the first and second districts is correctable.

8. The method according to claim 7, further comprising: determining, when a read instruction is issued from the external host device, whether or not the first data has been written to the first and second districts on the basis of a history of write to the first and second districts;

reading the data which has been written from one of the first and second districts when the first data is written to the first and second districts on the basis of the history of write;

determining whether or not the first data read from the one of the first and second districts, when it is determined that the first data has been written to the first and second districts, on the basis of the history of write, is correctable; and

executing a read operation when the first data is determined not to have been written to the first and second districts on the basis of the history of write.

10

9. A memory system comprising:

a first memory;

a second memory;

a first memory controller; and

a second memory controller,

wherein

the second memory controller is configured to issue a write command to write first data to both of the first memory and the second memory,

the first memory controller is configured to receive the write command and write the first data to both of the first memory and the second memory,

the second memory controller is configured to issue a read command to read the first data from one of the first memory and the second memory,

the first memory controller is configured to output the first data read from the one of the first memory and the second memory to the second memory controller,

the first memory controller is configured to determine whether or not the first data read from the one of the first memory and the second memory is correctable based on a result of an error correction, and

the first and second memory controllers are configured to perform issuing the write command, and each of issuing the read command and determining whether or not the first data is correctable when executing a data write in reply to the write command.
